ABSTRACT

In many applied problems, it is necessary to stabilize a system at some optimal operating point which is a priori unknown. One of the powerful tools to tackle such problems is extremum seeking theory, which allows to minimize (or maximize) the output of the system using only some limited information. This talk presents a novel approach for generating model-free extremum seeking controllers based on Lie bracket approximation techniques. The proposed algorithms exploit time-periodic control inputs with output-dependent coefficients. Conditions for the practical asymptotic stability and asymptotic stability in the sense of Lyapunov are proposed depending on the properties of the system and control vector fields. The obtained results are illustrated by numerical simulations and experiments with a mobile robot.

We hope to see you there!
